This study reports the phase transformation behaviour associated with electrolytic manganese dioxide (EMD) utilized as the positive electrode active material for aqueous zinc-ion batteries.

By 2025, adoption of Battery Grade Electrolytic Manganese Dioxide is expected to accelerate, driven by the surge in electric vehicle production and renewable energy projects.

Electrolytic Manganese Dioxide (EMD) sits at the intersection of alkaline and lithium-ion battery chemistries, making demand highly sensitive to the twin engines of mobility and storage.

In this application, manganese, usually in the form of manganese dioxide and sulphate, is primarily used as a cathode material in battery cells.
